### Problem Statement

Find the roots of the following quadratic equations by factorisation.

$$\sqrt{2}x^2 + 7x + 5\sqrt{2} = 0 \tag{2.1}$$

#### Solution

#### Theoritical Solution-

Checking roots of equation exist or not,

$$b^2 - 4ac \ge 0 \tag{3.1}$$

$$=49-4(\sqrt{2})(5\sqrt{2}) \tag{3.2}$$

$$=9\tag{3.3}$$

This means roots of equation exist.

And its roots are given by

$$x = \frac{b - \sqrt{b^2 - 4ac}}{2a}, \frac{b + \sqrt{b^2 - 4ac}}{2a}$$
 (3.4)

$$x = -\sqrt{2}, -\frac{5}{\sqrt{2}} \tag{3.5}$$

### **NEWTON-RAPHSON METHOD**

**Update Equation:** 

$$x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n)} \tag{4.1}$$

### Steps:

- 1. Start with an initial guess  $x_0$ .
- 2. Define the function f(x) and its derivative f'(x).
- 3. Iterate using:

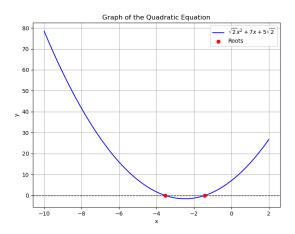

$$x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n)}$$
 (4.2)

until convergence, i.e.,

$$|x_{n+1} - x_n| < \text{tolerance} \tag{4.3}$$

4. Stop if  $f'(x_n)$  is close to zero to avoid division by zero.

# Plot by Finite Difference Method

## FINDING ROOTS USING :-EIGENVALUES

The quadratic equation

$$ax^2 + bx + c = 0 (6.1)$$

Its Companion Matrix

$$A = \begin{pmatrix} 0 & -\frac{c}{a} \\ 1 & -\frac{b}{a} \end{pmatrix} \tag{6.2}$$

Companion matrix for  $\sqrt{2}x^2 + 7x + 5\sqrt{2} = 0$ 

$$A = \begin{pmatrix} 0 & -5 \\ 1 & -\frac{7}{\sqrt{2}} \end{pmatrix} \tag{6.3}$$

### QR-DECOMPOSITION:-GRAM-SCHMIDT METHOD

Let,

$$A = QR \tag{7.1}$$

Q is an  $m \times n$  orthogonal matrix

R is an  $n \times n$  upper triangular matrix.

Given a matrix  $A = [a_1, a_2, \dots, a_n]$ , where each  $a_i$  is a column vector of size  $m \times 1$ .

Normalize the first column of A:

$$\mathbf{q_1} = \frac{\mathbf{a_1}}{\|\mathbf{a_1}\|} \tag{7.2}$$

For obtaining each column  $a_i$ , subtract the projections of the previously obtained orthonormal vectors from  $a_i$ :

$$\mathbf{a}_{i+1} = \mathbf{a}_i - \sum_{k=1}^{i-1} \langle \mathbf{a}_i, \mathbf{q}_k \rangle \mathbf{q}_k$$
 (7.3)

## QR-DECOMPOSITION:-GRAM-SCHMIDT METHOD

Normalize the result to obtain the next column of Q:

$$\mathbf{q_i} = \frac{\mathbf{a_i}}{\|\mathbf{a_i}\|} \tag{8.1}$$

Repeat this process for all columns of A.

We can compute the elements of R by taking the dot product of the original columns of A with the columns of Q:

$$A = QR \tag{8.2}$$

$$Q^{\top}A = Q^{\top}QR \tag{8.3}$$

$$Q^{\top} A = R \quad Q^{\top} Q = I \tag{8.4}$$

After, this method we will get the matrix A in form of QR.

# **QR-ALGORITHM**

Let  $A_0 = A$ .

For each iteration  $k=0,1,2,\ldots$ :- We got the QR decomposition of  $A_k$ , such that:

$$A_k = Q_k R_k \tag{9.1}$$

 $Q_k$  is an orthogonal matrix  $(Q_k^\top Q_k = I)$ .

 $R_k$  is an upper triangular matrix.

Then, form the next matrix  $A_{k+1}$  as:

$$A_{k+1} = R_k Q_k \tag{9.2}$$

Note:-The Eigenvalues of Matrix doesn't change in QR iteration because the orthogonal matrix  $Q_k$  preserves the lengths and angles of vectors.

$$A_0 = A_1 = A_2 = \dots = A_k \tag{9.3}$$

Repeat Step 2 until  $A_k$  converges to an upper triangular matrix T. The diagonal entries of T are the eigenvalues of A. The eigenvalues will be the roots of the Equation.
